b Stable Target combinations across research cities

62 combinations | All 429 cities with at least one observed combination

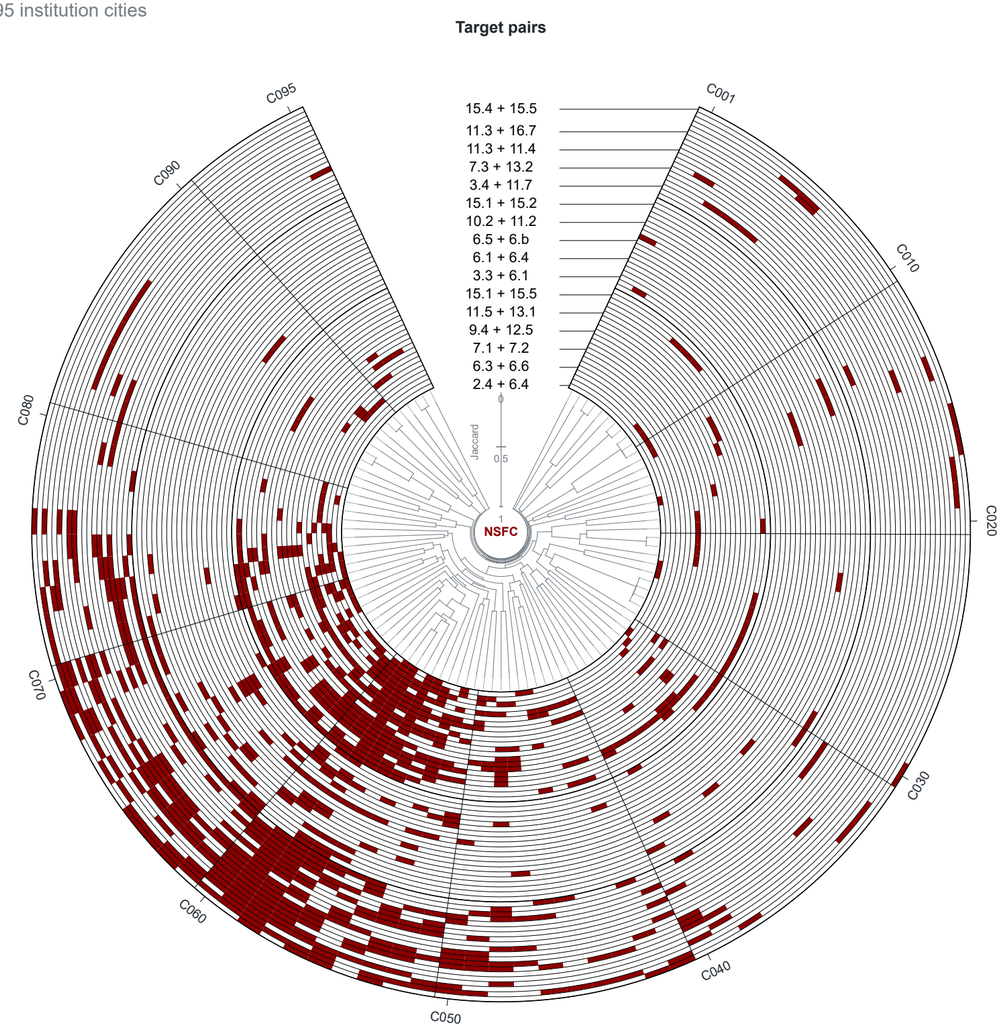

a NSF

334 institution cities

b NSFC

95 institution cities

Observed in NSF | Observed in NSFC | Not observed | City-profile clustering

Each spoke = one city; each ring = one Target pair. Pair order is identical in both countries.

Inner to outer: 22 pairs stable in both countries, 20 in NSF only, 20 in NSFC only; black arcs mark boundaries.

Trees use binary Jaccard distance and average linkage; branches indicate similarity, not collaboration.

Selected rings are labelled with their Target codes. All 62 pairs, city names and coverage counts are in the index.
